

# HyperSpell

Last Updated Friday, 18 May 2007

HyperSpell is a menu item that gives quick access to Mac OS X's built-in spellchecker. All you do is click on HyperSpell's icon in the menu bar and enter the word, or words, that you want spellchecked. Words that are misspelled appear with a red underline. You can then control-click (or right-click) on the misspelled words to reveal a list of possible spellings. HyperSpell features:

- Instant access to Mac OS X's built-in spellchecker from any application (Even from Carbon applications).
- Clipboard integration.
- Native Cocoa interface. New in 1.3
- Added a popup menu so that all corrections can be done using the keyboard. The menu will popup under a misspelled word and give you a selection of possible corrections. You can select one of the suggestions using the arrow keys on the keyboard or you can press Return to skip to the next misspelled word without making any changes.
- HyperSpell now properly activates the application that it was called from so that whatever window you were working in previously will be active for you to paste the corrected text into.
- The corrected text is now copied to the clipboard so that it can be pasted into the application you were working in.

Price: \$10

System Requirements: Mac OS X 10.2
